The Cost Impact of Application and Context Aware Networks

Table of Contents

1	Introduction	1	
2	Application-oriented networking		
	2.1 Technical opportunities and potential advantages	4	
	• 2.1.1 Application integration	5	
	• 2.1.2 The chance of global optimization	7	
	2.2 The market of intelligent networks	7	
	• 2.3 The study	7	
	• 2.3.1 System design	8	
3	How to model applications and communications requirements		
	3.1 Scenario	13	
	3.2 The Requirements Model	13	
	• 3.2.1 Sites	14	
	• 3.2.2 Paths	16	
	• 3.2.3 Applications	17	
	• 3.2.4 User Groups	22	
	3.3 Device types model	23	
	• 3.3.1 Link Type	23	
	• 3.3.2 Router Type	25	
	• 3.3.3 Card Type	25	
	• 3.3.4 Server Type	25	
4	The Solution Model		
	4.1 Introduction to the Solution Model	29	
	4.2 Delay time	30	
	• 4.2.1 Routing Table	31	
	• 4.2.2 Device path	31	
	• 4.2.3 Sequence of devices: general rules	32	
	• 4.2.4 Protocol translation rules	36	
	• 4.2.5 Application caching rules	36	
	• 4.2.6 Set of used devices	37	
	• 4.2.7 Queue model	38	
	• 4.2.8 General method to calculate delay	39	
	• 4.2.9 Definition of flow	42	
	4.3 Definition of devices	43	
	• 4.3.1 Router card	46	
	• 4.3.2 Router	46	
	• 4.3.3 Link	48	
	• 4.3.4 Server Farm	51	
5	Optimization Algorithm		
	5.1 Independent variables in the Solution Model	53	
	5.2 Tabu Search	54	
	5.3 Server farm and application placement	57	
	• 5.3.1 The initial solution	58	
	• 5.3.2 Moving applications and farms	59	
	5.4 Card placement	62	
	• 5.4.1 Tabu search	62	
	5.5 Path selection and device sizing	63	
	• 5.5.1 First sizing of links, routers and cards	63	
	• 5.5.2 First sizing of server farms	65	
	• 5.5.3 Configuration of a solution	67	
	• 5.5.4 Upgrade and downgrade a configuration	68	
	• 5.5.5 Sizing for delay	69	
6	Results		
	6.1 Scenario with an ASP	73	
	• 6.1.1 Scenario description	73	
	• 6.1.2 Results	74	
	6.2 Scenario without ASP	82	
	• 6.2.1 Scenario description	82	
	• 6.2.2 Results	82	
	• 6.3 Conclusions	90	
<hr/>			
Appendix			
<hr/>			
Software tool and device database			
	A.1 Software tool	95	
	A.2 Database of device types	95	
	• A.2.1 Link types	95	
	• A.2.2 Other device types	95	
<hr/>

Application-oriented networking represents a first step towards the integration between software, hardware and networks. The benefits of application-oriented networking lie in sharing application components among communicating users. This enables scale economies, since common application components are shared and their services are accessed by a higher number of users. The most straightforward example of these advantages is protocol translation, which shifts middleware functionalities into routers that can be crossed by application-level messages originating from any user site.

Both servers and network hardware can experience a decrease in their load. In some cases, user requests do not need to reach a server to be managed, but may hit their answer along the way inside a router equipped with an application-level card. For example, application-level caching can significantly decrease network traffic and server load. Furthermore, it can improve performance by providing users with faster responses.

The range of application components that can be moved to the network is vast, including application-level message routing, security, visibility, application optimization and extensibility. This breadth indicates that current implementations of application-oriented networking represent the tip of the iceberg. Any shared application component can be moved to network processing. In this way, the burden of developing, installing, managing and maintaining shared components can be alleviated and the quality of service can increase accordingly, by outsourcing common services to external providers. However, these changes must be justified by corresponding economic benefits. To what extent applications should be shifted to the network? What is the magnitude of savings? Who reaps the benefits of application-oriented networking? Application-oriented net-

working provides additional degrees of freedom to the design of the overall ICT (Information and Communication Technology) infrastructure. Servers and routers compete for the allocation of application components. Routers can be expected to win a share of application processing only when system requirements allow sufficient scale economies.

The purpose of this research is to investigate the results of an overall optimization of ICT design by leveraging the additional degrees of freedom offered by the application-oriented abilities of networks. The book tackles these design issues with a comprehensive approach. An overall model of the ICT infrastructure and corresponding design methodology are provided to face the overall optimization. Costs are modelled as an empirical design variable that drives the identification of the optimum.

Analyses cover multiple scenarios with application-level caching and format translation. The optimization goal is to decide whether to allocate these application components to router cards and to evaluate corresponding savings with respect to the traditional card-free scenario. Specifically, we assess the Total Cost of Ownership (TCO) of the ICT infrastructure, which includes both acquisition and management costs of technology components. Percent TCO savings represent the indicator measuring the benefits of application-oriented networking.

The presentation is structured as follows. Chapter 2 discusses the state of the art of application-oriented networking. Chapters 3, 4 and 5 present the formal model and optimization algorithm used in this book's empirical analyses. Chapter 6 reports optimization results in a broad range of scenarios and provides an assessment of the economic benefits of application-oriented networking.
